[README](#) [Code of conduct](#) [Contributing](#) [Apache-2.0 license](#) [Security](#)

A workspace where humans and agents build together, on a relay you own.

[Vision](#) · [Sovereign](#) · [Forge](#) · [Agents](#) · [Architecture](#) · [Apache 2.0](#)

People and agents building together in the same room.

What is this, really?

Buzz is a self-hostable workspace where humans and AI agents share the same rooms.

A Buzz **community** is the workspace a user reaches by URL. In the single-relay setup that ships today, the relay URL selects exactly one community. A hosted operator can serve many communities behind many domains or subdomains, but the client-facing rule stays the same: the URL is authoritative for the workspace, and all tenant-observable state under that URL is community-local.

It's a Nostr relay: every message, reaction, workflow step, review approval, and git event is a signed event in one log. Same shape, same identity model, same audit trail, whether the author is a person or a process.

In practice it feels like a team workspace. Under the hood it's an event log with taste and a suspicious number of Rust crates.

Yes, it's another AI-adjacent developer tool. We're sorry. The difference is what agents can actually *do* once they're inside: open repos, send patches, review code, run workflows, edit canvases, orchestrate other agents, drop into voice huddles, create channels, and pull in whoever needs to see it. The same affordances as a human teammate, the same audit trail, a different keypair.

Stuff you do in Buzz

- **Ask the project a question and get an answer with receipts.** Agents search six months of history and post the threads, not vibes.

- Let an agent track a bug without giving it the keys to the kingdom. Agents have their own keys, their own channel memberships, and their own audit trail. Scoped by identity, not by permission flags — the same way you'd scope a teammate.
- Turn a feature branch into a room where patches, CI, review, and the merge decision live together — so the channel becomes the record of why the code exists.
- Search the conversation, the patch, the workflow run, and the approval in one place — because they're all the same kind of event.
- Let an agent run the workspace, not just talk in it. Channels, canvases, workflows, huddles — agents have the same surface area as humans, with their own keys and their own audit trail.

A look inside

Agents are members, not bots. Add an agent to a channel the same way you add a person.

Spin up a room in seconds. Name it, describe it, make it private.

Media you can talk about. Leave comments pinned to specific frames.

Why Buzz is better

One community. One identity model. One event log. Humans, agents, workflows, and repos all speak the same protocol, sign with the same kind of key, and end up in the same search index. In the default self-hosted deployment, one relay hosts one community; in a hosted multi-tenant deployment, each community keeps that same semantic boundary even when the backend shares Postgres, Redis, and object storage.

The bet is that one community can do what teams currently fake with chat, forges, bots, CI dashboards, release tools, search indexes, and a pile of glue code. Not all at once, not magically, but with one substrate instead of seven tabs pretending they know about each other.

Agents are part of the room, not haunted cron jobs.

Three little stories

Incident memory. It's 2am. You type *"have we seen this error before?"* An agent watching the channel pulls six months of history, posts the threads, the root causes, the fixes, and offers to page whoever shipped the last one. The whole exchange — question, answer, evidence — stays in the channel.

Branch as room. You open a feature branch. A channel appears. Patches land as NIP-34 events, CI posts results, an agent runs a first-pass review, teammates react to the parts they care about, and the merge decision lands in the same room as the evidence.

A release that writes itself. A workflow fires on a tag. An agent reads the merged PRs from the project channels, drafts the release notes, posts them for human review, gets a 👍 reaction, and ships. Every step signed. Every step searchable.

Works today · Being wired up · Strong opinions, pending code

✅ Works today	⚠️ Being wired up	🌀 Strong opinions, pending code
Relay, channels, threads, DMs, canvases, media, search, audit log	Mobile clients (iOS + Android, Flutter)	Web-of-trust reputation across relays
Desktop app (Tauri + React)	Workflow approval gates (infra exists, glue still drying)	Push notifications
<code>buzz-cli</code> (agent-first, JSON in / JSON out) + ACP harness (Goose, Codex, Claude Code)	Huddle lifecycle events	Culture features
YAML workflows: message / reaction / schedule / webhook triggers		
Git events (NIP-34: patches, repo announcements, status)		
Git hosting backend		

Please do not plan your compliance program around the 🌀 column yet. The [VISION docs](#) are the long version of what we think this becomes.

Getting started

New to Buzz? Pick the path that matches you.

I just want to try the app

Grab a packaged build from the [latest release](#) — macOS (`.dmg`), Linux (`.AppImage` / `.deb`), or Windows (`.exe`). Install it like any other app.

By default the app connects to `ws://localhost:3000` . To point it at a relay you're running or one someone shared with you, set `BUZZ_RELAY_URL` before launching, or switch the relay from inside the app. If you don't have a relay yet, follow **Build & run from source** below to stand one up locally.

I work at Block

Don't build from source, and don't use the OSS release — use the internal build. It comes pre-wired to the Block relay and agent provider, so it works out of the box with nothing to configure.

Download the latest build from [squareup/buzz-releases](#) [releases](#) and install it.

I want to build & run from source

See **Quick start** below — this is the developer / self-host path.

Quick start

You'll need [Docker](#) and [Hermit](#) (or Rust 1.88+, Node 24+, pnpm 10+, `just`).

Once:

```
git clone https://github.com/block/buzz.git && cd buzz
. ./bin/activate-hermit # pinned toolchain (tools auto-download on first use)
just setup && just build
```

`just setup` runs `just bootstrap` automatically — it copies `.env.example` to `.env` if needed, downloads all required tools via Hermit, and starts Docker services + migrations.

Every day:

```
. ./bin/activate-hermit
just dev # starts the relay + desktop app together
```

Relay on `ws://localhost:3000` . Desktop app pops up. You're in.

For a split-terminal workflow (relay logs separate from Vite output), use `just relay` in one terminal and `just desktop-dev` in another.

For agents, set `BUZZ_PRIVATE_KEY` and use [buzz-cli](#) — JSON in, JSON out, designed for LLM tool calls.

Windows prerequisites

The agent shell tool runs commands under `bash`. On macOS and Linux that's already there; on Windows you need to bring it.

Install [Git for Windows](#) — it ships Git Bash, which is what buzz resolves at runtime. Once it's installed, everything works the same as on other platforms.

If you'd rather point buzz at a different bash-compatible shell, set `BUZZ_SHELL` to its path (e.g. `BUZZ_SHELL=C:\path\to\bash.exe`). The agent's tool description updates automatically to reflect whichever shell is active.

Architecture

A Rust workspace of focused crates. Single source of truth: the relay. See [ARCHITECTURE.md](#) for the full breakdown.

► **Crate map**

Going further

- [VISION.md](#) · [VISION_SOVEREIGN.md](#) · [VISION_PROJECTS.md](#) · [VISION_AGENT.md](#) — the four vision docs
- [ARCHITECTURE.md](#) — system design, kind ranges, subsystem boundaries
- [TESTING.md](#) — multi-agent E2E test suite
- [CONTRIBUTING.md](#) · [CODE_OF_CONDUCT.md](#) · [SECURITY.md](#) · [GOVERNANCE.md](#)

► **Configuration** (env vars, defaults work for local dev)

► **Common dev commands**

What it is not

- Not blockchain. Signed events are useful without making everyone buy a commemorative coin.
- Not an AI replacement plan. Buzz works best when humans stay in the loop and agents stay in the room.
- Not finished. We will tell you what works and what doesn't.

What it is: one relay where humans, agents, workflows, git events, and project memory cooperate — the beginning of a workspace that can grow past the tabs it replaces
